Implicit Differentiation

Implicit differentiation is a technique in calculus for finding the derivative of a relation defined implicitly (that is, a relation between variables x and y that is not explicitly solved for one variable in terms of the other).

1.1 Implicit Differentiation Procedure

Consider an equation that defines a relationship between x and y:

$$F(x, y) = 0$$

To find the derivative of y with respect to x, we differentiate both sides of this equation with respect to x, treating y as an implicit function of x:¹

$$\frac{d}{dx}F(x,y) = \frac{d}{dx}0$$

Applying the chain rule during the differentiation on the left side of the equation gives:

$$\frac{\partial F}{\partial x} + \frac{\partial F}{\partial y} \frac{dy}{dx} = 0$$

Finally, we solve for $\frac{dy}{dx}$ to find the derivative of y with respect to x:

$$\frac{\mathrm{d}y}{\mathrm{d}x} = -\frac{\frac{\partial F}{\partial x}}{\frac{\partial F}{\partial y}}$$

This result is obtained using the implicit differentiation method.

¹This $\frac{d}{dx}$ form of the derivative is the same as y' said as taking the derivative of y with respect to x

1.2 Example

Consider the equation of a circle with radius r:

$$x^2 + y^2 = r^2$$

First, we will find $\frac{dy}{dx}$ without implicit differentiation. Newxt, we will apply implicit differentiation to get the same result.

1.2.1 Without Implicit Differentiation

First, we need to rearrange the equation to solve for y:

$$y^2 = r^2 - x^2$$
$$y = \pm \sqrt{r^2 - x^2}$$

We take the derivative of y by applying the Chain Rule:

$$\frac{dy}{dx} = \frac{1}{2 \pm \sqrt{r^2 - x^2}} \cdot (-2x) = \frac{-x}{\pm \sqrt{r^2 - x^2}}$$

Notice the denominator of this fraction is the same as the solution we found for y, $y = \pm \sqrt{r^2 - x^2}$. So, we can also represent this as:

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{-x}{y}$$

1.2.2 With Implicit Differentiation

With implicit differentiation, we assume y is a function of x and apply the Chain Rule.

$$\frac{d}{dx}[x^2 + y^2] = \frac{d}{dx}[r^2]$$

For x^2 and r^2 , we take the derivative as we normally would.² For y^2 , we apply the Chain Rule, as outlined above.³

$$2x + 2y\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

²The $\frac{d}{dx}$ part disappears when taking the derivative of x, as the derivative of x with respect to x is just regular differentiation.

³Applying the chain rule is only allowed as y is not the variable we were taking the derivative with respect to.

Solving for $\frac{dy}{dx}$, we find

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{-x}{y}$$

, which is the same result as we found without implicit differentiation.

1.3 Folium of Descartes

It was relatively easy to rearrange the equation for a circle to solve for y, but that is not always the case. Consider the equation for the folium of Descartes (yes, that Descartes!):

$$x^3 + y^3 = 3xy$$

It is much more difficult to isolate y in this equation. In fact, were we to do so, we would need three separate equations to completely describe the original equation.

1.3.1 Example: Tangent to Folium of Descartes

In this example, we will use implicit differentiation to easily find the tangent line at a point on the folium.

- (a) Find $\frac{dy}{dx}$ if $x^3 + y^3 = 6xy$
- (b) Find the tangent to the folium $x^3 + y^3 = 3xy$ at the point (2,2)
- (c) Is there any place in the first quadrant where the tangent line is horizontal? If so, state the point(s).

Solution:

(a)
$$\frac{d}{dx}[x^3 + y^3] = \frac{d}{dx}[3xy]$$

$$3x^{2} + 3y^{2} \frac{dy}{dx} = 3x \frac{dy}{dx} + 3y$$
$$x^{2} + y^{2} \frac{dy}{dx} = x \frac{dy}{dx} + y$$

Rearranging to solve for $\frac{dy}{dx}$:

$$\frac{\mathrm{d}y}{\mathrm{d}x}(y^2 - x) = y - x^2$$

$$\frac{\mathrm{dy}}{\mathrm{dx}} = \frac{y - x^2}{y^2 - x}$$

(b) We already have the coordinate point, (2,2), so to write an equation for the tangent line, all we need is the slope. Substituting x = 2 and y = 2 into our result from part (a):

$$\frac{\mathrm{dy}}{\mathrm{dx}} = \frac{2 - 2^2}{2^2 - 2} = \frac{-2}{2} = -1$$

This is the slope, m. Using the point-slope form of a line, our tangent line is y-2=-(x-2).

(c) Recall that in the first quadrant, x > 0 and y > 0. We will set our solution for $\frac{dy}{dx}$ equal to 0:

$$\frac{y-x^2}{y+2-x}=0$$

which implies that

$$y - x^2 = 0$$

Substituting $y = x^2$ into the original equation:

$$x^{3} + (x^{2})^{3} = 3(x)(x^{2})$$
$$x^{3} + x^{6} = 3x^{3}$$

Which simplifies to

$$x^6 = 2x^3$$

Since we have excluded x = 0 by restricting our search to the first quadrant, we can divide both sides by x^3 :

$$x^3 = 2$$
$$x = \sqrt[3]{2} \approx 1.26$$

Substituting $x \approx 1.26$ into our equation for y:

$$y\approx 1.26^2=1.59$$

Therefore, the folium has a horizontal tangent line at the point (1.26, 1.59).

1.4 Practice

Exercise 1

[This problem was originally presented as a no-calculator, multiple-choice question on the 2012 AP Calculus BC Exam.] If $\arcsin x = \ln y$, what is $\frac{dy}{dx}$?

Working Space ———

Answer on Page 7

Exercise 2

[This problem was originally presented as a no-calculator, multiple-choice question on the 2012 AP Calculus BC Exam.] The points (-1,-1) and (1,-5) are on the graph of a function y=f(x) that satisfies the differential equation $\frac{dy}{dx}=x^2+y$. Use implicit differentiation to find $\frac{d^2y}{dx^2}$. Determine if each point is a local minimum, local maximum, or inflection point by substituting the x and y values of the coordinates into $\frac{dy}{dx}$ and $\frac{d^2y}{dx^2}$.

This is a draft chapter from the Kontinua Project. Please see our website (https://kontinua.org/) for more details.

Answers to Exercises

Answer to Exercise 1 (on page 5)

Using implicit differentiation, we see that:

$$\frac{d}{dx}\arcsin x = \frac{d}{dx}\ln y$$

$$\frac{1}{\sqrt{1-x^2}} = \frac{1}{y} \frac{\mathrm{d}y}{\mathrm{d}x}$$

Multiplying both sides by y to isolate $\frac{dy}{dx}$, we find that:

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{y}{\sqrt{1 - x^2}}$$

Answer to Exercise 2 (on page 5)

First, we need to find $\frac{d^y}{dx^2}$:

$$\frac{d}{dx}\frac{dy}{dx} = \frac{d}{dx}x^2 + \frac{d}{dx}y$$
$$= 2x + \frac{dy}{dx} = 2x + x^2 + y$$

At (-1,-1), $\frac{dy}{dx}=(-1)^2+(-1)=0$ and $\frac{d^2y}{dx^2}=2(-1)+(-1)^2+(-1)=-2<0$. Since the slope of y is zero and the graph of y is concave down, (-1,-1) is a local maximum. At (1,-5), $\frac{dy}{dx}=1^2+-5=-4\neq 0$ and $\frac{d^2y}{dx^2}=2(1)+1^2+(-5)=-2\neq 0$. Since neither the first nor second derivative of y are zero, (1,-5) is neither a local extrema nor an inflection point.
