Binary Search

As mentioned in the last chapter, you are going to make a priority queue for use with Dijkstra's Algorithm. Using it will look like this:

```
import kpqueue
myqueue = pqueue.PriorityQueue()
myqueue.add(long_beach, 0) # Inserts first city and its cost
myqueue.add(san_diego, 14) # Puts San Diego after Long Beach
myqueue.add(los_angeles,12) # Inserts LA between Long Beach and San Diego
current_city = myqueue.pop() # Returns first city (Long Beach) and removes it
```

Now, if an item gets a new priority, we need to remove it and reinsert it in the new spot.

```
myqueue.add(city_a, 16) # Puts it last in the queue
myqueue.update(city_a, 16, 13) # Moves it to between LA and San Diego
```

1.1 A Naive Implementation of the Priority Queue

Create a file called kpqueue.py. Let's do a simple implementation that stores the priority and the data as tuple. And we will keep it sorted by the priority. If two tuples have the same priority, we will sort by the data.

Type this in to kpqueue.py:

```
class PriorityQueue:
    def __init__(self):
        self.list = []

# Return and remove the first item
    def pop(self):
        if len(self.list) > 0:
            return self.list.pop(0)
        else:
            return None

def __len__(self):
        return len(self.list)

def update(self, value, old_priority, new_priority):
```

```
old_pair = (old_priority, value)
    self.list.remove(old_pair)
    self.add(value, new_priority)

def add(self, value, priority):
    pair = (priority, value)
    # Add it at the end
    self.list.append(pair)
    # Resort the list
    self.list.sort()
```

This will work fine, but it could be much more efficient:

- Every time we add a single element, we resort the whole list.
- The function remove is searching the list sequentially for the item to delete.

In a minute, we will revisit these inefficiencies and make them better.

1.2 Using the Priority Queue

We are going to change graph.py to use the priority queue. While we are doing so, why don't we also shrink the memory footprint of our program a bit.

Notice that as the algorithm is running, each node is in one of three states:

- Unseen: In the earlier implementation, these were the nodes with math.inf as their cost.
- Seen, but not finalized: These are "unvisited", but don't have math.inf as their cost.
- Finalized: These are the "visited" nodes we know that their cost won't decrease any more.

We can shrink the memory foot print by not putting the unseen into the dist dictionary at all. And instead of a separate set for "unvisited", what if we moved finalized nodes and their distances into a separate dictionary?

Rewrite the cost_from_node function in graph.py:

```
# Is this the first time I am seeing the node?
if v not in seen_dist:

# Insert into the seen_dict, prev, and priority queue
seen_dist[v] = alt
prev[v] = current_node
pqueue.add(v, alt)

else: # v has been seen. Is this a cheaper route?
old_dist = seen_dist[v]
if alt < old_dist:
    # Update the seen_dict, prev, and priority queue
seen_dist[v] = alt
prev[v] = current_node
pqueue.update(v, old_dist, alt)

return (finalized_dist, prev)</pre>
```

This should be have exactly the same result, except for the unreachable nodes. If you have a graph that is not connected, there will be nodes that cannot be reached from the origin. In the old version, these had a cost of math.inf. Now, they will just not be in the dictionary at all. So, change cities.py to deal with this:

```
if nyc in cost_from_long_beach:
    nyc_cost = cost_from_long_beach[nyc]
    print(f"\n*** Total cost from Long Beach to NYC: ${nyc_cost:.2f} ***")

    path_to_nyc = graph.shortest_path(prev, nyc)
    print(f"\n*** Cheapest path from Long Beach to NYC: {path_to_nyc} ***")
else:
    print("You can't get to NYC from Long Beach")
```

If you run cities.py now, it should behave exactly like the old version.

However, there is a bug. It will rear its head if two cities with the same cost are in the priority queue together. Change cities.py so that Denver and Pheonix have the same cost:

```
graph.WeightedEdge(12, long_beach, los_angeles)
graph.WeightedEdge(19, los_angeles, denver)
graph.WeightedEdge(19, los_angeles, pheonix)
```

Now try running it. You should get an error:

```
TypeError: '<' not supported between instances of 'Node' and 'Node'
```

What happened? The loc_for_pair method is comparing tuples made up of a float and a Node. The float comes first in the tuple, so that is compared first. However, if the two tuples have the same priority, it then compares nodes.

The error statement says, "Nodes don't have a less-than method; I don't know how to compare them."

Each Node lives at an address in memory. You can get that address as a number using the id function. The ID is unique and constant over the life of the object. It is a rather arbitary ordering, but it will work for this problem. Add a method to your Node class:

```
# Nodes will be ordered by their location in memory
def __lt__(self, other):
    return id(self) < id(other)</pre>
```

Fixed.

Now, let's make the priority queue more efficient.

1.3 Binary Search

The phone company in every town used to print a thing called a phone book. The names and phone numbers were arranged alphabetically. As you might imagine, these books often had more than a thousand pages.

If you were looking for "John Jeffers", you would not start at the first page and read sequentially until you reached his name. You would open the book in the middle, and see a name like "Mac Miller", then think "Jeffers comes before Miller". You would then split the pages in your left hand in half and see a name like "Hester Hamburg" and think "Jeffers comes after Hamburg". You would then split the pages in your right hand, and continue on like this until you found the page with "John Jeffers" on it.

That is binary search.

Binary Search is a search algorithm that finds the position of a target value within a sorted array. The binary search algorithm works by repeatedly dividing the search interval in half. If the target value is equal to the middle element of the array, the position is returned. If the target value is less than or greater than the middle element, the search continues in the lower or upper half of the array, respectively.

1.4 Algorithm

The binary search algorithm can be described as follows:

- 1. If the array is empty, the search is unsuccessful, so return "Not Found".
- 2. Otherwise, compare the target value to the middle element of the array.
- 3. If the target value matches the middle element, return the middle index.
- 4. If the target value is less than the middle element, repeat the search with the lower half of the array.
- 5. If the target value is greater than the middle element, repeat the search with the upper half of the array.
- 6. Repeat steps 2-5 until the target value is found or the array is exhausted.

```
class PriorityQueue:
   def __init__(self):
       self.list = []
   # Return and remove the first item
   def pop(self):
       if len(self.list) > 0:
           return self.list.pop(0)
       else:
           return None
   def __len__(self):
       return len(self.list)
   def add(self, value, priority):
       pair = (priority, value)
       i = self.loc_for_pair(pair)
       self.list.insert(i, pair)
   def update(self, value, old_priority, new_priority):
       old_pair = (old_priority, value)
       i = self.loc_for_pair(old_pair)
       del self.list[i]
       self.add(value, new_priority)
   def loc_for_pair(self, pair):
       # The range where it could be is [lower, upper)
       # Start with the whole list
       lower = 0
       upper = len(self.list)
       while upper > lower:
            next_split = (upper + lower) // 2
```

```
v = self.list[next_split]
if pair < v: # pair is to the left
    upper = next_split
elif pair > v: # pair is to the right
    lower = next_split + 1
else: # Found pair!
    return next_split
return lower
```

If you try running it now, it should work perfectly.

You now have a graph class that will find the cheapest path quickly, even if it has thousands of nodes with thousands of edges.

This is a draft chapter from the Kontinua Project. Please see our website (https://kontinua.org/) for more details.
